Arnimallee 14 D-14195 Berlin-Dahlem Germany

1. Introduction.
2. Element specific magnetizations in trilayers.
3. Determination of orbital- and spin- magnetic moments;
XMCD sum rules.
Magnetic Anisotropy Energy (MAE) and anisotropic μ_L .
4. Induced magnetism at interfaces.
5. New developments, outlook

1. Introduction: XAS

X-ray Absorption Spectroscopy is the most appropriate technique for element specific investigations.

$L_{3,2}$ edges of 3d elements

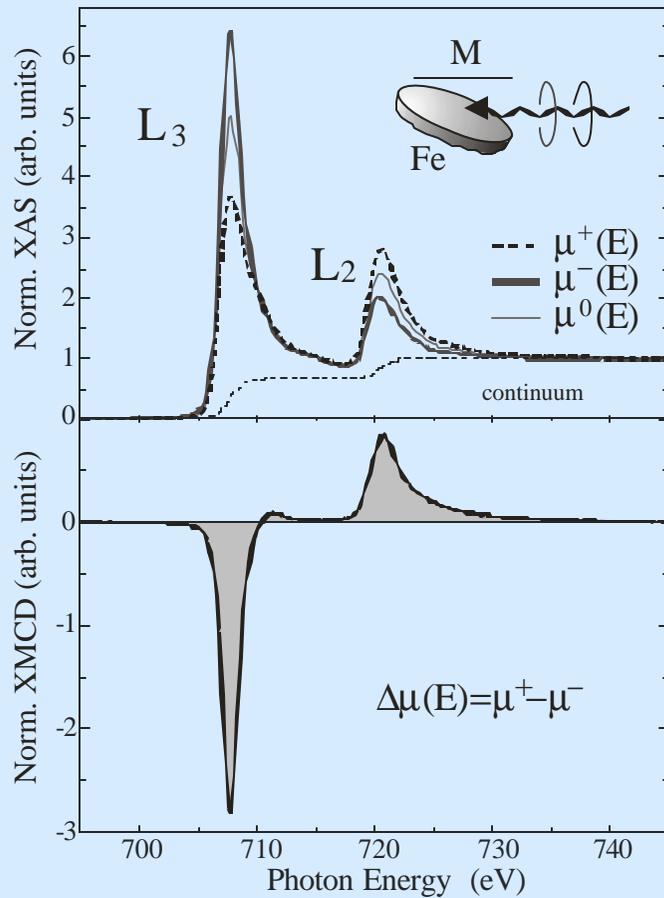

Note: the intensity of the $2p \rightarrow 3d$ dipole transitions (E1) is proportional to the number of unoccupied final state (i.e. 3d- holes).

Appendices/References

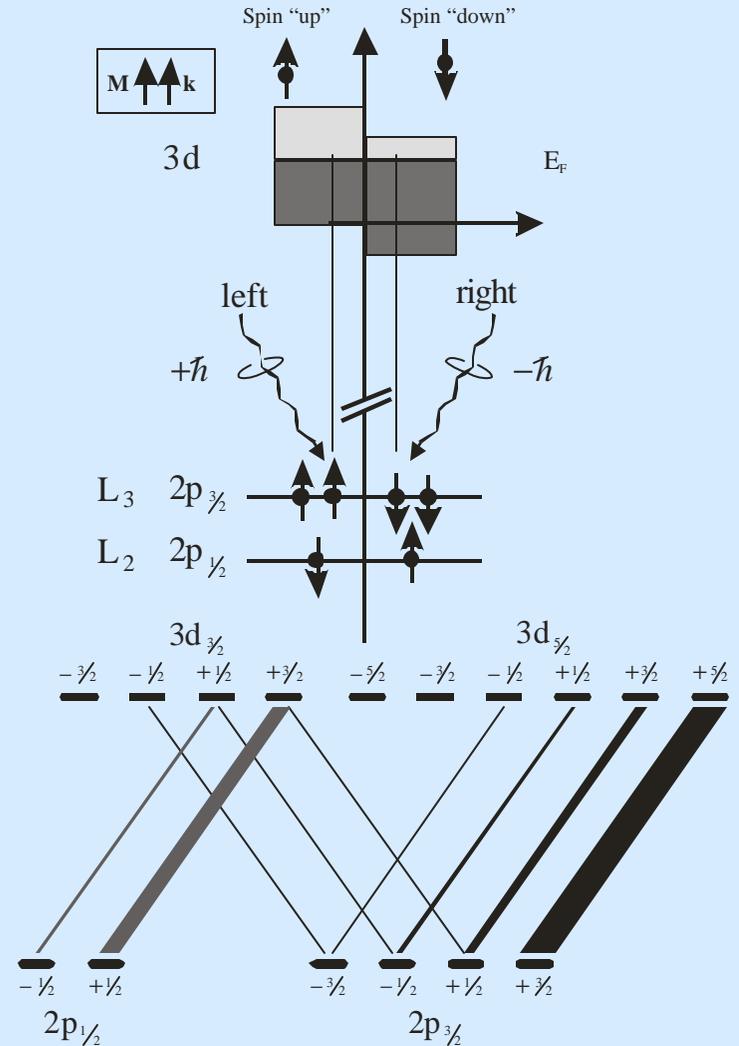

- In this lecture we will **not** discuss the equipment/apparatus, but rather focus on application of XAS in magnetism.
- Concerning XAS-technique there exist many review articles e.g.
J. Stöhr: *NEXAFS Spectroscopy*, Springer Series in Surface Science **25**, 1992;
H. Wende: *Recent advances in the x-ray absorption spectroscopy*, Rep. Prog. Physics **67**, 2105 (2004).
- See also lectures A13 J. Vogel; A14 Y. Joly;
A'15 (Trieste) F. Sirotti; A''15 (Saclay) M. Sacchi.
- In the soft X-ray regime (VUV) one needs to work in vacuum. For nanomagnetism one wants to prepare and work anyway in UHV (*in situ* experiments).

X-ray Magnetic Circular Dichroism

Faraday – effect in the X-ray regime (Gisela Schütz, 1987)

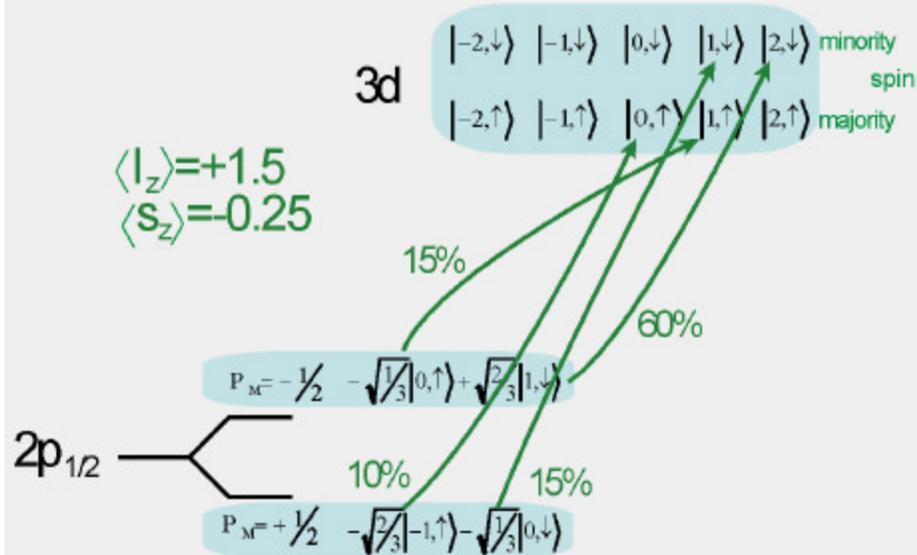

XMCD signal is a measure of the magnetization

2. Element specific magnetizations in trilayers

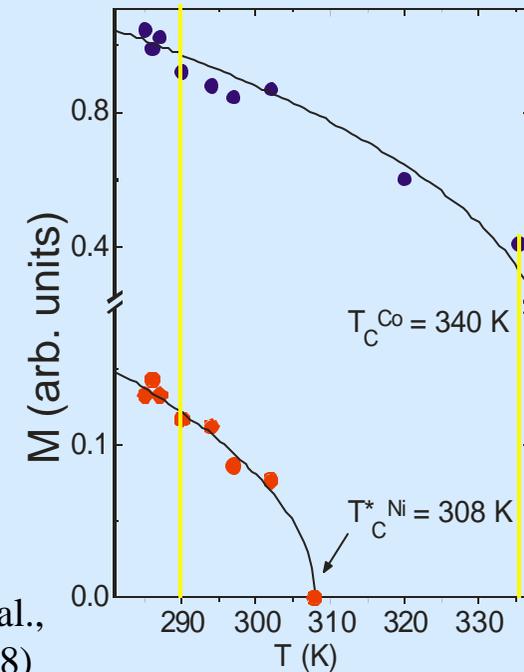

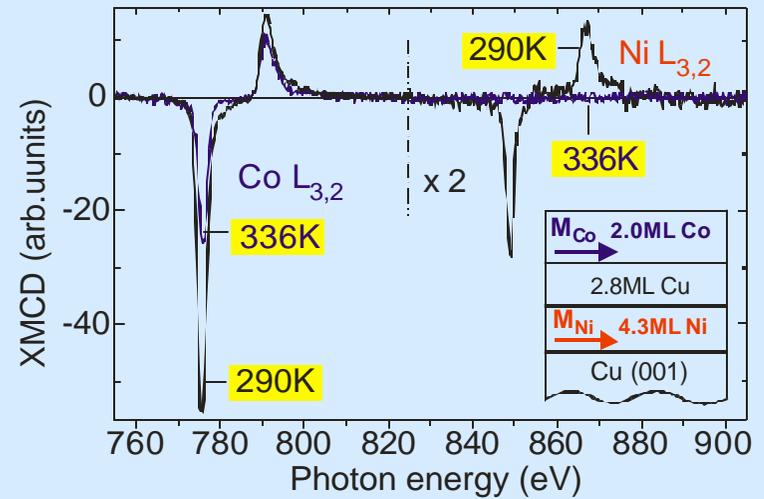

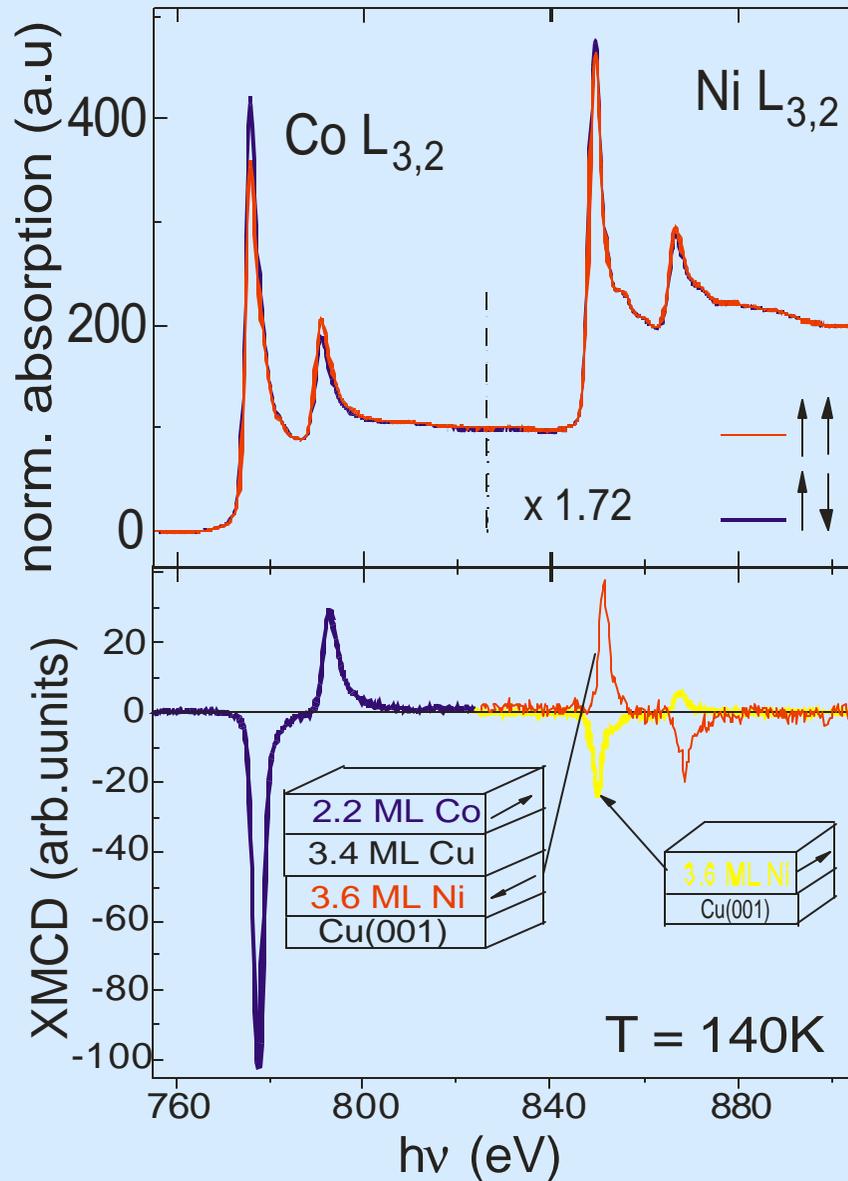

A trilayer is a prototype to study magnetic coupling in multilayers.

What about element specific Curie-temperatures ?

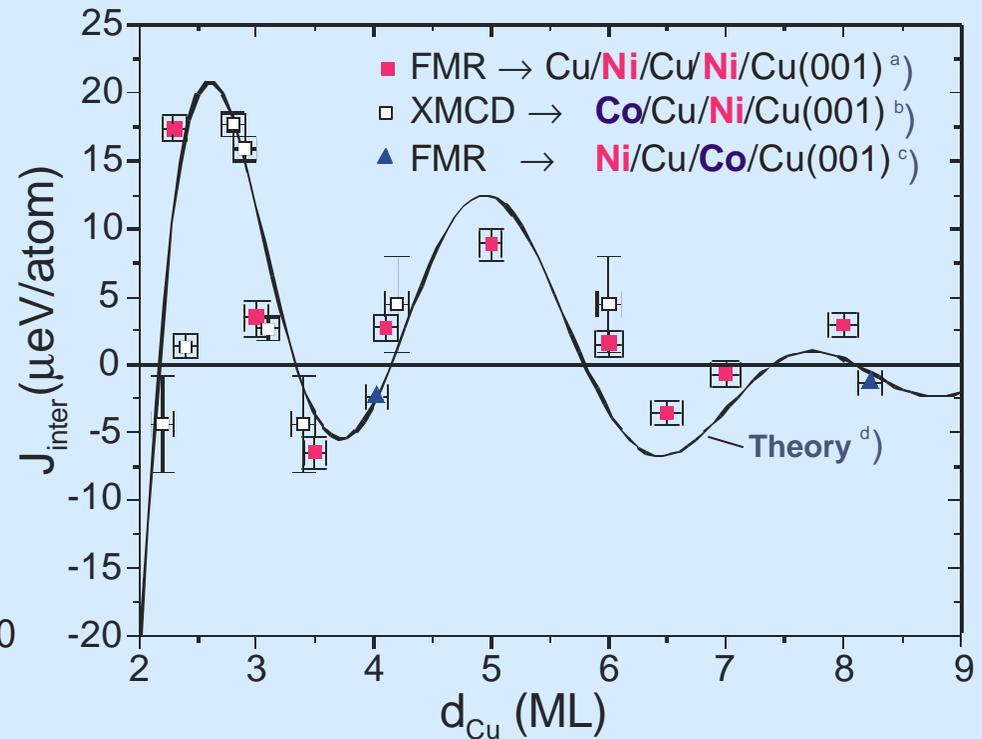

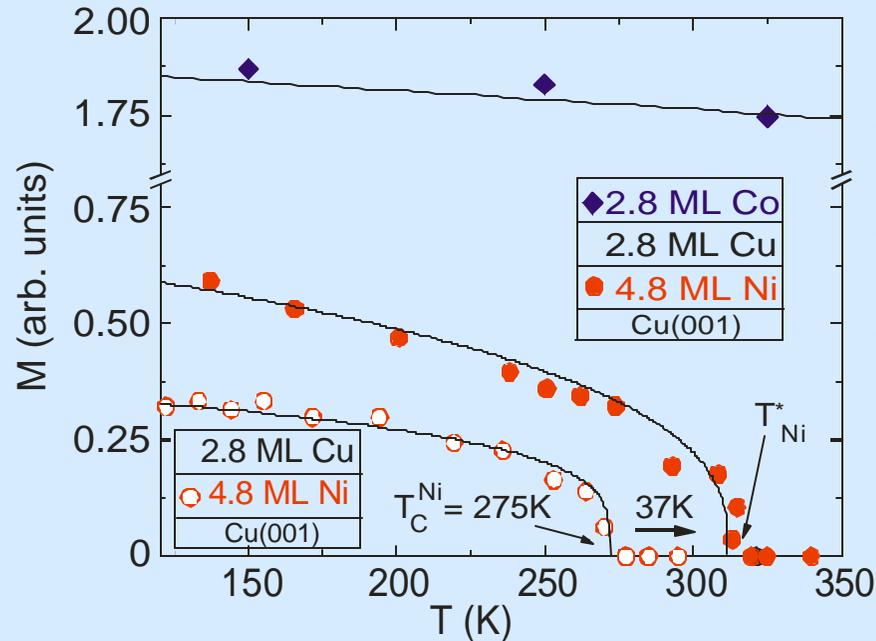

- Two trivial limits: (i) $d_{\text{Cu}} = 0 \Rightarrow$ direct coupling like a Ni-Co alloy
(ii) $d_{\text{Cu}} = \text{large} \Rightarrow$ no coupling, like a mixed Ni/Co powder
- BUT** $d_{\text{Cu}} \approx 2 \text{ ML} \Rightarrow ?$

Spin-Spin correlation function $\frac{\partial}{\partial t} \langle\langle S_i^+ S_j^- \rangle\rangle \rightarrow$

$$S_i^z S_j^+ \approx \langle S_i^z \rangle S_j^+ - \langle S_i^- S_i^+ \rangle S_j^+ - \langle S_i^- S_j^+ \rangle S_i^+ + \dots$$

← RPA →

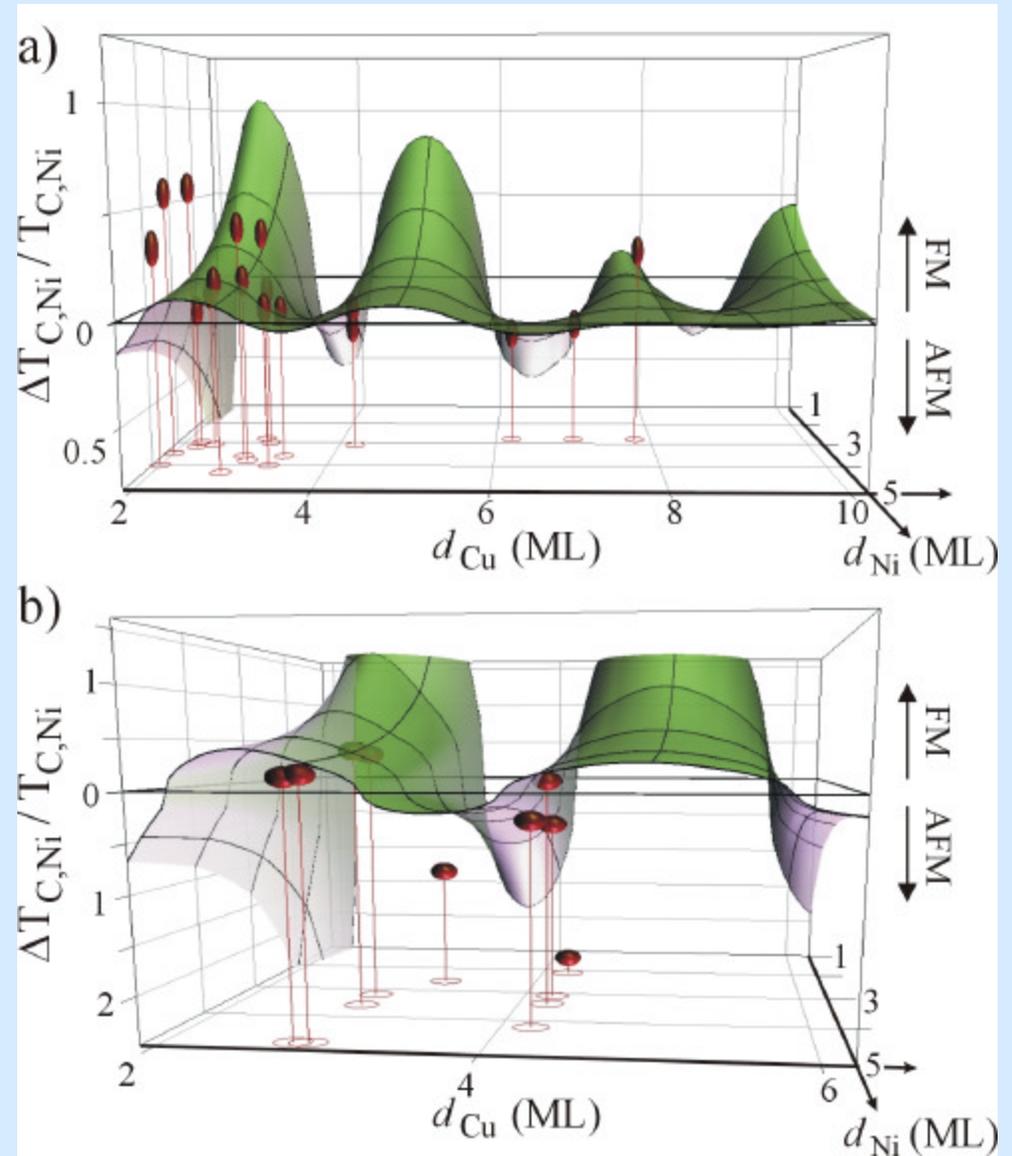

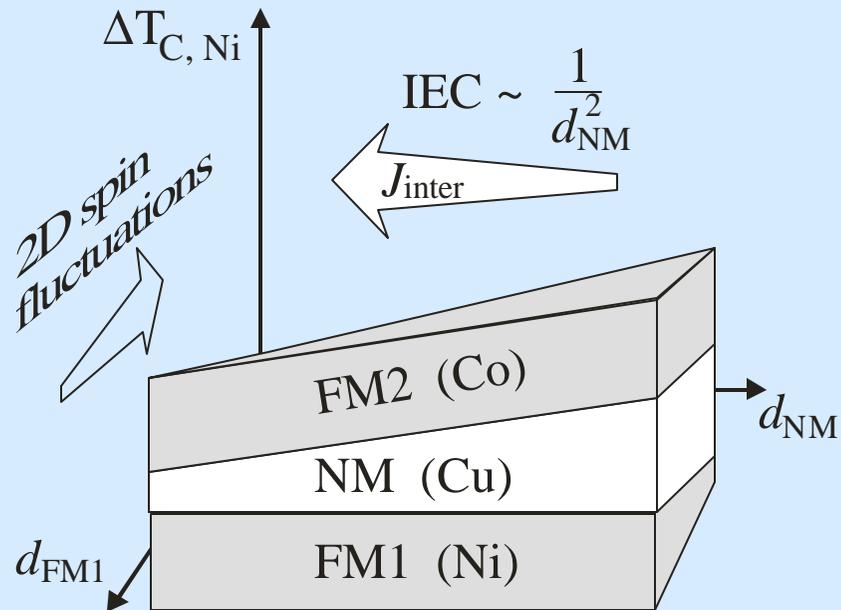

$\langle S_i^z \rangle S_j^+$ mean field ansatz (Stoner model) is insufficient to describe spin dynamics at interfaces of nanostructures

Single band Hubbard model:
Simple Hartree-Fock (Stoner) ansatz is insufficient
Higher order correlations are needed to explain T_C -shift

Evidence for giant spin fluctuations

PRB 72, 054447, (2005)

3. Determination of orbital- and spin- magnetic moments

Which technique measures what?

μ_L, μ_S in UHV-XMCD

$\mu_L + \mu_S$ in UHV-SQUID

μ_L / μ_S in UHV-FMR

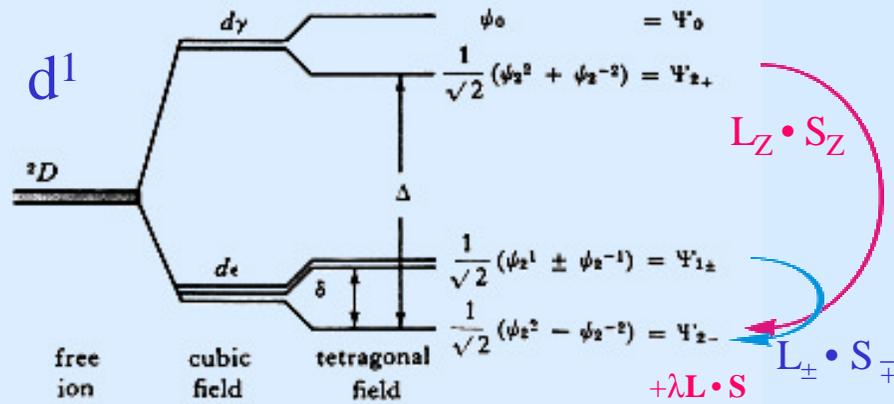

For FMR see: J. Lindner and K. Baberschke
In situ Ferromagnetic Resonance:
An ultimate tool to investigate the coupling in
ultrathin magnetic films
J. Phys.: Condens. Matter **15**, R193 (2003)

per definition:

- 1) spin moments are isotropic
- 2) also exchange coupling $\mathbf{J} \mathbf{S}_1 \cdot \mathbf{S}_2$ is isotropic
- 3) so called *anisotropic exchange* is a (hidden) projection of the orbital momentum into spin space

Orbital magnetism in second order perturbation theory

effective Spin Hamiltonian

Splitting of the 2D term by a tetragonally distorted cubic field.

$$\mathbf{y}_{2-} \equiv (2)^{-1/2} \{ |2\rangle - |-2\rangle \} \equiv |2-\rangle$$

The orbital moment is quenched in cubic symmetry

$$\langle 2- | L_z | 2- \rangle = 0,$$

but not for tetragonal symmetry

$$\mathcal{H} = \sum_{i,j=1}^3 [\overbrace{\beta g_e(\delta_{ij} - 2\lambda\Lambda_{ij})}^{g_{\text{exp}}}] S_i H_j - \underbrace{\lambda^2 \Lambda_{ij}}_{B_2^0 \rightarrow K_2^0} S_i S_j + \text{diamagnetic terms in } H_i H_j \quad (3-23)$$

where Λ_{ij} is defined in relation to states ($n > 0$) as

$$\Lambda_{ij} = \sum_{n \neq 0} \frac{\langle 0 | L_i | n \rangle \langle n | L_j | 0 \rangle}{E_n - E_0} \quad (3-24)$$

$\langle 0 | \mu_B \mathbf{H} \cdot \mathbf{L} | n \rangle \langle n | \lambda \mathbf{L} \cdot \mathbf{S} | 0 \rangle$ $\langle 0 | \lambda \mathbf{L} \cdot \mathbf{S} | n \rangle \langle n | \lambda \mathbf{L} \cdot \mathbf{S} | 0 \rangle$

In the principal axis system of a crystal with axial symmetry, the $\underline{\Lambda}$ tensor is diagonal with $\Lambda_{zz} = \Lambda_{\parallel}$ and $\Lambda_{xx} = \Lambda_{yy} = \Lambda_{\perp}$. Under these conditions, \mathcal{H} of (3-23) can be simplified, since

$$S_x^2 + S_y^2 = S(S+1) - S_z^2$$

to give

$$\mathcal{H} = g_{\parallel} \beta H_z S_z + g_{\perp} \beta (H_x S_x + H_y S_y) + D [S_z^2 - \frac{1}{3} S(S+1)] \quad (3-25)$$

where

$$\begin{aligned} g_{\parallel} &= g_e(1 - \lambda\Lambda_{\parallel}) \\ g_{\perp} &= g_e(1 - \lambda\Lambda_{\perp}) \\ D &= \lambda^2(\Lambda_{\perp} - \Lambda_{\parallel}) \end{aligned} \quad (3-26)$$

Magnetic Anisotropy Energy (MAE) and anisotropic μ_L

1. Magnetic anisotropy energy = f(T)
2. Anisotropic magnetic moment \neq f(T)

$$MAE = \frac{1}{2} M \cdot dB \sim \frac{1}{2} M \cdot B \sim \frac{1}{2} 200 \cdot 200 \text{ G}^2$$

$$MAE \sim 2 \cdot 10^4 \text{ erg} / \text{cm}^3 \sim 0.2 \mu\text{eV} / \text{atom}$$

$\approx 1 \mu\text{eV}/\text{atom}$ is very small compared to

$\approx 10 \text{ eV}/\text{atom}$ total energy **but all important**

$$g_{\parallel} - g_{\perp} = g_e \lambda (\Lambda_{\perp} - \Lambda_{\parallel})$$

anisotropic $\mu_L \leftrightarrow$ MAE

$$D = \frac{\lambda}{g_e} \Delta g$$

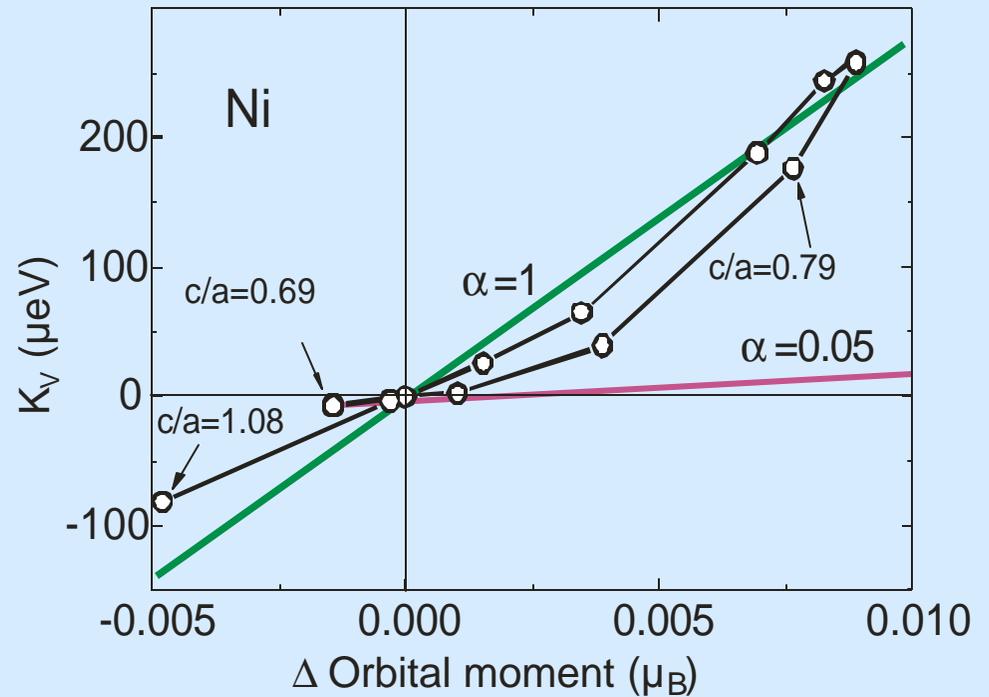

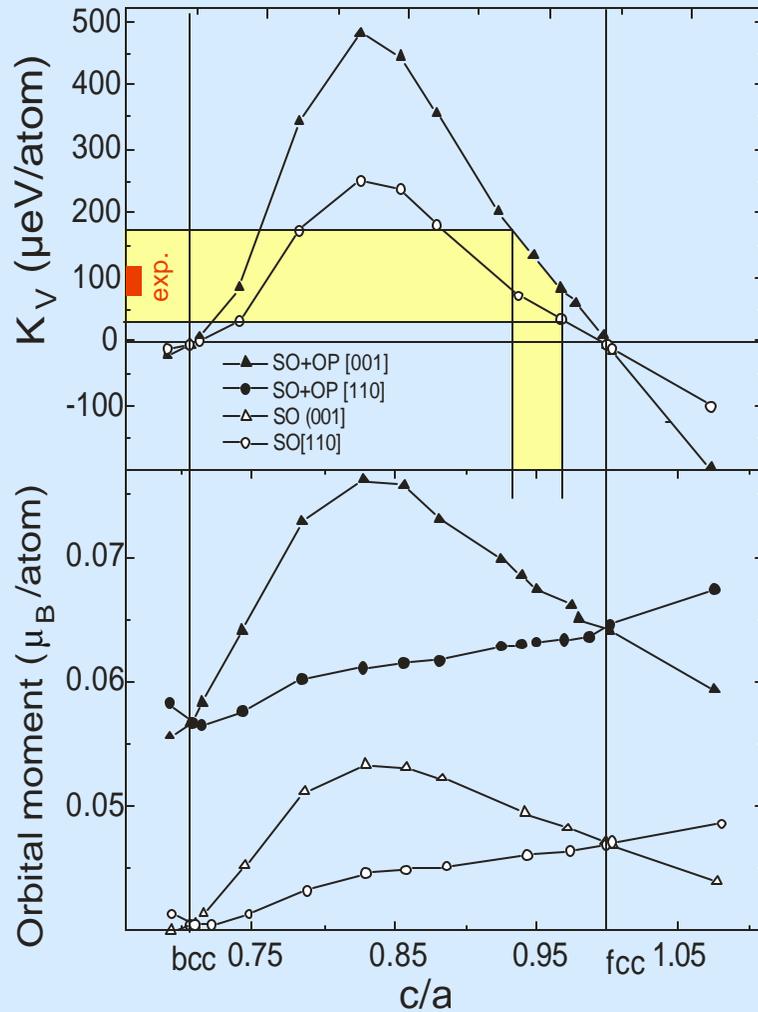

$$MAE \propto \frac{\chi_{LS}}{4\mu_B} \Delta\mu_L \quad \text{Bruno ('89)}$$

Characteristic energies of metallic ferromagnets

binding energy	1 - 10 eV/atom
exchange energy	10 - 10 ³ meV/atom
cubic MAE (Ni)	0.2 $\mu\text{eV}/\text{atom}$
uniaxial MAE (Co)	70 $\mu\text{eV}/\text{atom}$

Abstract

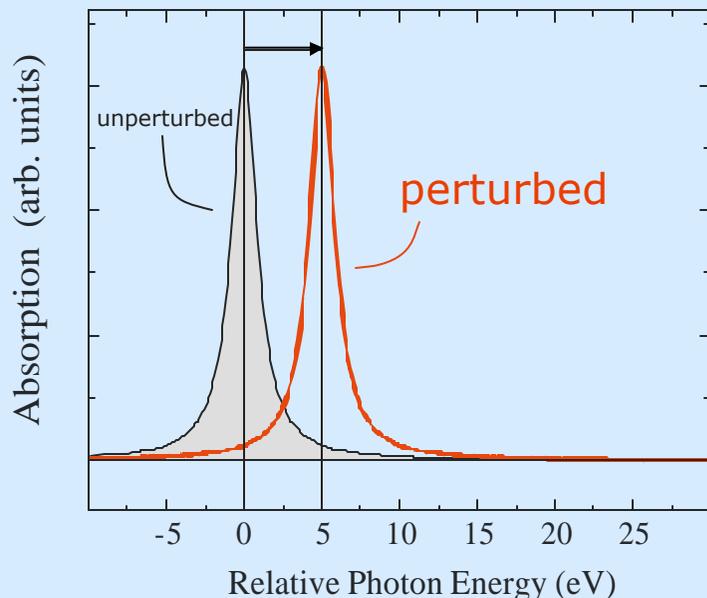

Sum rules relate the integrated signals of the spin-orbit split core levels to ground state properties, such as the spin-orbit coupling, magnetic moments and charge distribution. These rules give the zeroth moments of the spectral distribution. It is shown how this can be generalized to higher-moment statistical analysis

n_H

- ⇒ double pole model describes branching ratio for light 3d's
- ⇒ regime where sum rules fail

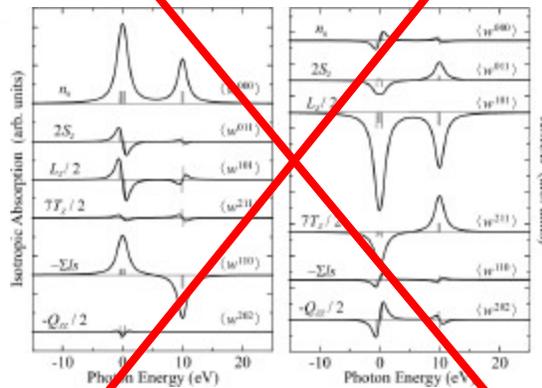

Summary

- gap-scan technique \Rightarrow systematic investigation of XAS, XMCD fine structure
- development double pole approximation
 \Rightarrow correlation energies (Ti: $M_{11}=3.07$ eV, $M_{22}=-0.56$ eV, $M_{12}=0.54$ eV)
- experiment \Rightarrow failure of spin sum rule \leftrightarrow core-hole interaction
- theory \Rightarrow correlation energies as input for theory
- \Rightarrow future ab initio calculations must include core-hole correlation effects

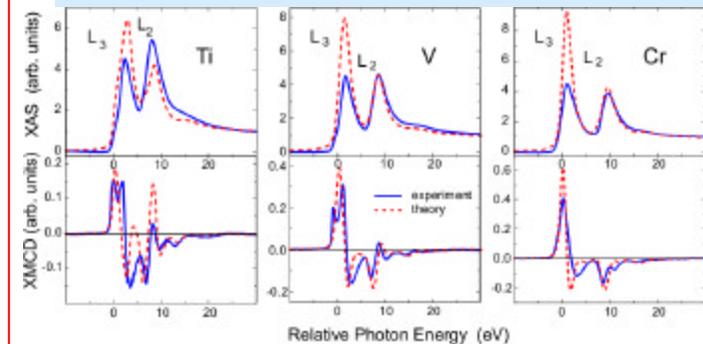

1) integral SR

2) MMA

3) calculation of full $\mu(E)$ ✓

see: Recent advances in x-ray absorption spectroscopy

H. Wende, Rep. Prog. Phys. **67** (2004) 2105-2181

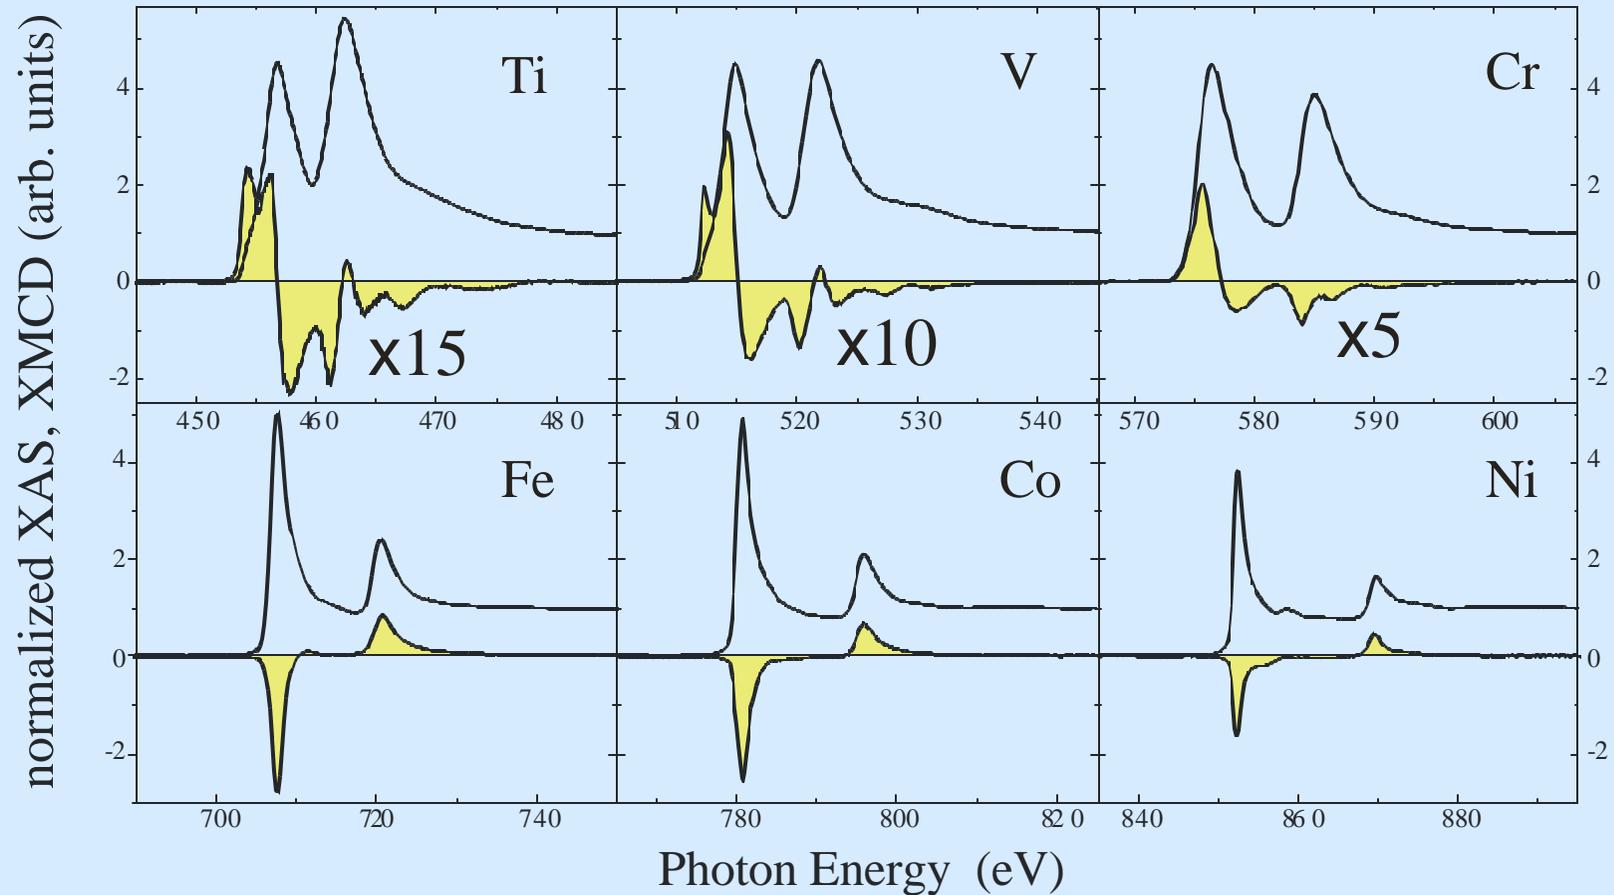

-
- All spectroscopic techniques do not restrict themselves to measure the intensity (area under the resonance) only.
i.e.: integral sum rules.
 - A resonance signal contains a resonance position, a width, an asymmetry profile, etc.
 - The optimum is given if theory can calculate the full profile of the resonance, in our case $\mu(E)$ i.e. the spectral density.

Conclusion, Future

During last few years: enormous progress in

- Theory:**
- calculate $\mu(E)$, spin dependent spectral distribution
 - full relativistic calculations
 - real (not ideal) crystallographic structures

- Experiment:**
- higher $\Delta E/E$, detailed dichroic fine structure
 - undulator, gap-scan technique, constant high P_C
 - element-selective microscopy, probe of “non-magnetic” constituents

- Future:**
- core hole effects:
 - change of branching ratio for early 3d elements
 - effect on XMCD unknown!
 - correct determination of $\Delta \mu_L$ and MAE with XMCD (x30)
 - correction for spin- and energy-dependence of matrix elements
