Boltzmann approach to the spin Hall effect revisited and
electric field modified collision integrals

J. Kailasvuori

(Dated: December 30, 2008)

The intrinsic contribution to the spin Hall effect in a 2DEG with non-magnetic impurities is studied in a quantum Boltzmann approach. It is shown that if the steady state response is perturbative in the spin-orbit coupling parameter $\lambda$, then the precession term—vital for Dyakonov-Perel relaxation and the key to the spin Hall effect in previous similar Boltzmann studies—must be left out to first order in spin-orbit coupling. In such a case one would have that to lowest order in the parameters electric field, spin-orbit coupling, impurity strength and impurity concentration there is no intrinsic contribution to the spin Hall effect, not only for a Rashba coupling but for a general spin-orbit coupling. To cover all possible lowest order terms we consider also electric field induced corrections to the collision integral in the Keldysh formalism. However, these corrections turn out to be of second order in $\lambda$. For comparison we derive some familiar results in the case when the response is not assumed to be perturbative in $\lambda$.

I. INTRODUCTION

The idea in spintronics is to manipulate the electron spin for information storage and transfer, as done with the electron charge in electronics. Possible advantages could for example be smaller resistive losses, or the additional richness that comes from the non-scalar nature of spin. In the study of spin currents particular attention has been given to the spin Hall effect (SHE) in a two-dimensional degenerate electron gas (2DEG) with spin-orbit coupling. Perpendicular to an applied electric field, opposite spins travel in opposite directions, thus creating a spin current without a net charge current. Such a spin-current can lead to an accumulation of spin at the edges of a sample, although in contrast to the electrical charge analogy this is not given. An individual spin can change its direction, for example due to spin precession, and therefore the accumulated spin polarization is not a conserved quantity. The SHE opens up one possibility of manipulating spin with electric fields.

The experiments on the SHE are few and recent [1, 2, 3, 4, 5, 6] The theoretical side is in contrast very proliferous (see e.g. the reviews [7, 8, 9]) and still in recent years has there been an intense discussion about the different mechanisms and how to compare results reached by different formalisms. This discussion is closely related to the one on the anomalous Hall effect (AHE) [10], for example in the distinction between extrinsic (impurity related, e.g. skew scattering, side-jump etc) and intrinsic (band structure related) mechanisms. The latter could be due to strucutre inversion asymmetry of the confining potential (leading e.g. to a Rashba coupling) or due to bulk inversion asymmetry (allowing for a Dresselhaus coupling).

The earliest theoretical works on the SHE were done by Dyakonov and Perel in 1971 [11], who showed that a spin-orbit coupling leads to a spin current perpendicular to the electric field. The name Spin Hall effect was coined in 1999 [12]. A universal spin Hall conductivity in a 2DEG was proposed [13, 14, 15]. However, impurities were neglected in these studies. Many studies have later shown that universality is lost when impurities are taken into account [16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28]. On the other hand, there can still be topological edge modes, responsible for the quantum SHE (see e.g. ref. [29]).

The effect of non-magnetic impurities on the intrinsic contribution to the SHE has been studied using a Boltzmann approach [16, 17, 18, 19, 20, 21] as well as diagrammatic methods [22, 23, 24, 25, 26, 27, 28] like the Kubo formalism. The diagrammatic methods are more systematic and have a more general range. The Boltzmann approach offers more intuition, but has typically been implemented by identifying distinct processes or hand-picking different contributions rather than systematically covering all possible contributions through a formal approach. Within the Boltzmann language one finds several different approaches. We are going to use the quantum Boltzmann approach, which treats spin coherently.

This paper is going to deal with the intrinsic spin Hall effect in a steady-state calculation to first order in spin-orbit interaction. We attempt in a Keldysh derivation of the Boltzmann equation to account for all contributions present.

*Electronic address: kailas@physik.fu-berlin.de
to lowest order in electric field, in spin-orbit splitting and in strength and concentration of non-magnetic impurities. (Secs. III[V] and sec. X) The spin-orbit interaction $H_{\text{SO}} = \sigma \cdot b$ is chosen to be of the isotropic form $b = b(k)\hat{b}(\theta)$, where the unit vector $\hat{b}$ has a winding number $N$, i.e. $\hat{b}_x + i\hat{b}_y = e^{i\theta_0 + iN\theta}$ with $\theta_0$ being a constant.

Many recent theoretical studies come to the conclusion that the spin Hall effect vanishes for $N = \pm 1$ (e.g. for the Rashba and linear Dresselhaus spin-orbit couplings) for point-like impurities [16, 17, 18, 19, 20, 21, 22, 23, 25, 26, 27, 28] as well as finite range impurities [17, 18, 19, 21]. General arguments have been proposed to explain this vanishing. [27, 28] (Sec VII.) A nonzero result can be found in refs. 23, 24. With an alternative definition of spin currents, a nonzero result is also found in ref. 12.

For other odd $N$ the SHE is nonzero [15, 16], assumes a universal value in a specific limit [16], but depends otherwise on the range of the impurity potential and is therefore in general not universal, though it is independent of the spin-orbit splitting $b$, the overall strength of the impurity potential and of the impurity concentration [19]. We reproduce these results in sec. VI. Additionally, we give explicit results on the polarization and spin currents for the components of the spin parallel to the plane and calculate equilibrium spin currents.

We are also going to see that the above results on the SHE are based on the response not being perturbative in the spin-orbit coupling. If perturbativeness is assumed (sec. VIII), the spin-precession term—seemingly the prerequisite for a spin Hall current—must be left out to linear order in spin-orbit coupling, suggesting that to lowest order the intrinsic spin Hall effect is zero for arbitrary winding $N$ (sec. IX). Possible alternative contributions to the SHE from electric field induced corrections to the collision integral are discussed in sec. X. A contribution that we believe has not been discussed before in the Boltzmann approach turns out to be the only candidate when the precession term is absent. However, this contribution turns out to be of second order in spin-orbit splitting.

Leaving out the precession term leads to some formal difficulties in the case $N = \pm 1$. The Boltzmann equation becomes unsolvable. However, this can be remedied by including a small spin relaxation term (sec. IX). This could suggest that the SHE is zero for arbitrary winding number $N$ as well as finite range impurities [17, 18, 19]. General arguments have been proposed to explain this vanishing. [27, 28] (Sec VII.) A nonzero result can be found in refs. 23, 24. With an alternative definition of spin currents, a nonzero result is also found in ref. 12.

II. THE MODEL—INTRINSIC VERSUS EXTRINSIC

For a semiclassical Boltzmann description (see e.g. 30, 31, 32, 33) one needs the Wigner transformed one-particle Hamiltonian. For the spin-orbit (SO) coupled electrons we are going to study, it is

$$H(x, p, t) = a(k) + \sigma \cdot b(k) + e\phi(x, t)$$

with $e < 0$ and $k(x, p, t) = p - eA(x, t)$. We want to describe a 2d system with $x$ and $p$ chosen to lie in the $x, y$-plane. Throughout the paper $\hbar = 1$. In absence of spin-orbit coupling the dispersion is given by $a \propto k^2$, typically $a = k^2/2m$.

For the Rashba interaction $b := |b| = \lambda k$ and $\hat{b} := b/b = \hat{b}$, with $\lambda$ parametrizing the strength of the coupling. However, we want to consider an arbitrary odd-integer winding number $N$ in $b = b(k)\hat{b}(\theta)$ (with $\hat{b}_x + i\hat{b}_y = e^{i\theta_0 + iN\theta}$).

The energy bands are $\epsilon_k = a + sb$ with $s = \pm$ giving the sign of the spin along the spin quantization axis $\hat{b}$, i.e. $\sigma \cdot b\hat{b}_s = s|\hat{b}|$.

The total Hamiltonian $H_{\text{tot}} = H + H_{\text{imp}}$ also includes an impurity potential $V_{\text{imp}}(x) = \sum_n U(x - x_n)$ of charged, non-magnetic impurities at positions $x_n$. Including the spin orbit coupling experienced at impurities one has

$$H_{\text{imp}} = V_{\text{imp}} + \lambda_{\text{ext}}\sigma \cdot k \times \nabla V_{\text{imp}}.$$  

$\lambda_{\text{ext}}H_{\text{imp}}$ and $H_{\text{imp}}$ are treated very differently in the Boltzmann approach. $H$ enters linearly into the equation of motion, whereas $H_{\text{imp}}$ is in the Keldysh machinery turned into an impurity averaged self-energy to appear to quadratic order in the collision integral.

A spin-orbit coupling enters both through the intrinsic (i.e. band related) term $\sigma \cdot b$ and in the extrinsic (i.e. impurity related) term $\lambda_{\text{ext}}\sigma \cdot k \times \nabla V_{\text{imp}}$, and the consequences of the two are usually studied separately in the literature. This paper deals only with the intrinsic contribution to the spin Hall effect.

III. SEMICLASSICAL DESCRIPTION OF A SPIN-ORBIT COUPLED SYSTEM

In a Boltzmann description of an electron system with spin, the spatial degrees of freedom are treated semiclassically, whereas the treatment of the spin remains quantum mechanical. The state of the system is given by the $2 \times 2$-matrix valued distribution function $f_\sigma(x, p, t)$, here with the spin index $\sigma = \uparrow, \downarrow$. It is related to the equal time density matrix $\rho_{\sigma\sigma}(x_1, x_2)|_{t_2 = t_1} = \langle \Psi_{\sigma}^\dagger(x_2, t_1)\Psi_{\sigma}(x_1, t_1) \rangle$ by a Wigner transformation (see e.g. refs. 30, 31, 32, 33). In
absence of scattering one can derive the Boltzmann equation for $f$ by applying Heisenberg’s equation of motion on \( \rho(x_1, x_2) \), then identifying \( f_2 = t_1 \), Wigner transforming the result and gradient expanding it to first order. The approximation to stop at first order in gradient expansion is the semiclassical approximation, which relies on the external perturbations, such as electromagnetic potentials, changing negligibly on length and time scales of the de Broglie wavelength \( \lambda_B \) and time \( \tau_B = \lambda_B/v_F \).

From the matrix elements of the distribution function \( f \) one extracts the densities and current densities of charge and spin. The matrix elements are most conveniently expressed in the decomposition \( f = 1 f_0 + \sigma \mu f_\mu = f_0 + \sigma \cdot f \) in Pauli matrices (with \( \mu = x, y, z \)). (Throughout the paper we use the convention of summation over repeated indices.) Furthermore, we find it convenient to decompose the vector \( f = f_\mu \hat{b} + f_\sigma \hat{c} + f_z \hat{z} \) in its components along the basis vectors \( \hat{b}(\theta) \), \( \hat{z} \) and \( \hat{c}(\theta) = \hat{z} \times \hat{b}(\theta) \), analogous to the cylindrical basis vectors \( \hat{k}(\theta) := \hat{k}/k \), \( \hat{z} \) and \( \hat{\theta}(\theta) := \hat{z} \times \hat{k}(\theta) \).

The charge density \( e n \) and current density \( e \mathbf{j} \) in phase space are derived from \( e n = \text{Tr}(f \partial H/\partial \phi) \) and \( e \mathbf{j} = -\text{Tr}(f \partial H/\partial A) \), which yields

\[
\begin{align*}
n(x, k, t) := \text{Tr} f &= 2 f_0 = n^+ + n^- \\
j_i(x, k, t) := \text{Tr} (v_i f) &= 2 f_0 \partial_k a + 2 f : \partial_k b = n^+ v_i^+ + n^- v_i^- + \frac{2N_b}{k} f_\sigma \hat{\theta}_i
\end{align*}
\]

with \( i = x, y \). Here we introduced the velocity matrices \( v_i := \partial_k H = \partial_k a + \sigma \cdot \partial_k b \). The spin-independent part of the velocity is \( \partial_k a = : v_0 \). The band velocities are \( v^s := \partial_k \epsilon^s = (\langle \hat{b}\vert \mathbf{v} \hat{b} \rangle) = v^s \hat{k} \). The intra-band elements \( n^\pm := \langle \hat{b} \pm \vert \mathbf{f} \hat{b} \pm \rangle = f_0 \pm f_\sigma \) give the density of each spin band \( s = \pm \). The inter-band elements \( \langle \hat{b} \pm \vert \mathbf{f} \hat{b} \mp \rangle = f_z \pm if_\sigma \) are important for the coherent treatment of spin and are, for example, present in the last term of \( \mathbf{A} \), containing the Zitterbewegung of the spin-orbit coupled electrons.

The real space densities are obtained by integrating the phase space densities over momentum, \( e.g. \)

\[
j(x, t) = \int \frac{d^2 k}{(2\pi)^2} j(x, k, t). \tag{4}
\]

When not otherwise stated, densities are in this paper always assumed to be phase space densities.

The spin density, \( i.e. \) the polarization, is given by \( s^\mu = \frac{1}{2} \text{Tr}(\sigma^\mu f) = f_\mu \) (with \( h = 1 \)). There is not a unique way to define the spin current because spin polarization is not a conserved quantity. (For a proposal on a conserved spin current, see ref.\[34\].) For its implications on the SHE, see ref.\[18\] When band velocities coincide, \( i.e. \) \( v^s = v_0 \), then it is clearly \( \mathbf{j}^\mu = f_\mu v_0 \).

For the general case we choose the common definition

\[
j^\mu_i = \frac{1}{4} \text{Tr} \sigma^\mu \{ v_i, f \} = f_\mu \partial_k a + f_\sigma \partial_k b_\mu \tag{5}
\]

(with \( \{ A, B \} = AB + BA \)). The spin Hall effect is a real space current of \( z \)-component spins

\[
j^z = \int \frac{d^2 k}{(2\pi)^2} f_z v_0 = \frac{1}{e} \sigma_{\text{SH}} \hat{z} \times \mathbf{E} \tag{6}
\]

perpendicular to the an applied electric field \( \mathbf{E} \) along the plane. \( \sigma_{\text{SH}} \) is the spin Hall conductivity.

The Boltzmann equation in matrix form is given by

\[
i[H, f] + \partial_T f + \frac{1}{2} \{ v_i, \partial_x f \} + eE_i \partial_k f - \epsilon_{xij} eB_j \frac{1}{2} \{ v_i, \partial_k f \} = \mathcal{J}[f] \tag{7}
\]

where the matrix-valued functional \( \mathcal{J} \) is the collision integral. In components it reads (from now on the charge \( e \) in \( eE \) and \( eB \) is absorbed into the fields)

\[
\begin{align*}
\partial_t f_0 + \partial_x f_0 \partial_k a + \partial_x f : \partial_k b + E_i \partial_k f_0 + \epsilon_{xij} B_j \partial_k f_0 \partial_k a + \partial_k f : \partial_k b &= J_0 \\
2f \times b + \partial_t f + \partial_x f \partial_k a + \partial_x f_0 \partial_k b + E_i \partial_k f + \epsilon_{xij} B_j (\partial_k f_0 \partial_k a + \partial_k f_0 \partial_k b) &= \mathcal{J}
\end{align*}
\]

However, by virtue of definition \( [39] \) the equations \( [8] \) can be compactly written as

\[
\begin{align*}
\partial_t n + \partial_x \cdot \mathbf{j} + \partial_k \cdot (n \mathbf{E} + \mathbf{j} \times \mathbf{B}) &= 2J_0 \\
2(s \times \mathbf{b})^\mu + \partial_t s^\mu + \partial_x \cdot j^\mu + \partial_k \cdot (s^\mu \mathbf{E} + j^\mu \times \mathbf{B}) &= J_\mu
\end{align*}
\]

The left-hand side of the first equation is the same as for charged, spinless particles in an electromagnetic field. Apart from the spin-precession term, the second equation is of similar form. This is what one would expect since the electromagnetic field does not interact with the spin in the considered model but only with the charge that the spin sits on. The spin enters in a non-trivial way only through the precession term and through the collision integral.
IV. DERIVATION OF THE COLLISION INTEGRAL IN THE KELDYSH FORMALISM

The presence of, for example, two-body interactions or disorder averaged impurity interaction is in the Boltzmann approach described by the collision integral \( \mathcal{J} \). It is assumed that one is in the kinetic regime, where the de Broglie wavelength \( \lambda_B = 1/k \phi \) is much shorter than the scattering length \( \ell \). Like ref. [19] we use the Keldysh formalism (see e.g. refs. [30] [31] [52] [53]), but among other general methods we can mention the Nonequilibrium statistical operator formalism [34]. For disorder averaged impurities, see also the compact derivation in ref. [21].

The Keldysh derivation of the semiclassical Boltzmann equation with the collision term. This should be contrasted with the quasiclassical Boltzmann approach (see e.g. ref. [33]) where the integration is instead performed over \( |k| \) to obtain a distribution function \( f(x, \hat{p}, t, \Omega) \). This is the approach for example in refs. [19] and [20].

The Dyson equation can be written in two equivalent forms

\[ \hat{1} = (i\partial_t - H - \Sigma) \ast G \quad \text{or} \quad \hat{1} = G \ast (i\partial_t - H - \Sigma). \]  

(11)

The product involved here is the convolution product, the identity stands for \( \hat{1} := 1 \delta(x_1 - x_2) \delta(t_1 - t_2) \) and quantities are written in Keldysh matrix space with

\[ G = \begin{pmatrix} G^R & G^K \\ 0 & G^A \end{pmatrix} \quad \text{and} \quad i\partial_t - H - \Sigma = \begin{pmatrix} i\partial_t - H - \Sigma^R & -\Sigma^K \\ 0 & i\partial_t - H - \Sigma^A \end{pmatrix}. \]

(12)

Each element in these matrices is an infinite-dimensional matrix in real space indices, and in our case also a \( 2 \times 2 \) matrix in spin indices.

The two equations in (11) contain the same information. To derive kinetic equations one takes the difference of them, which for the Keldysh component yields

\[ (i\partial_t - H) \ast G^K - G^K \ast (i\partial_t - H) = \Sigma^R \ast G^K - G^K \ast \Sigma^A - G^R \ast \Sigma^K + \Sigma^K \ast G^A. \]

(13)

The right hand side is going to give the collision integral, which we only treat to lowest order in impurity concentration and impurity strength (first Born approximation),

\[ \Sigma_p = n_{\text{imp}} \int \frac{d^2p'}{(2\pi)^2} |U((p - p'))|^2 G^0_{p'p}, \]

(14)

with \( G^0 = G(\Sigma = 0) \). (\( \Sigma \) is diagonal in momentum space due to the disorder averaging of the impurity interaction.)

According to self-consistent Born-approximation we replace \( G^0\Sigma \) by \( G^K \). A crucial approximation comes with choosing the generalized Kadanoff-Baym Ansatz [33]

\[ G^K = i(G^R \ast h - h \ast G^A) + \ldots \]

(15)

where \( h := G^K|_{t_2 = t_1} \), which generalizes the quasiparticle approximation \( G^K = h(x, p, t)\delta(\Omega - \epsilon) \) for spinless electrons. The approximation can be considered to be an expansion in relaxation times of the system and corresponds to a Markov approximation.

The convolution product takes after Wigner transformation \( A(x_1, t_1, x_2, t_2) \rightarrow A(x, p, t, \Omega) \) the form \( A \ast B = Ae^{\mp D}B \) with the Poisson-bracket-like gradient. In a gauge invariant treatment valid when the electromagnetic fields are weak and vary slowly (see e.g. p. 344, Vol. 1 in ref. [30]), one introduces \( k(p, x, t) = p - A \) and \( \omega(\Omega, x, t) = \Omega - \phi \) and lets \( \{x, k, t, \omega \} \) become the new set of independent variables (i.e. \( \partial_{x, k} = 0 \)). This changes the gradient into

\[ D = \bar{\partial}_x \bar{\partial}_{k_x} - \bar{\partial}_{k_x} \bar{\partial}_x + \bar{\partial}_\omega \bar{\partial}_t - \bar{\partial}_t \bar{\partial}_\omega + E_i(\bar{\partial}_\omega \bar{\partial}_{k_i} - \bar{\partial}_{k_i} \bar{\partial}_\omega) + \epsilon_{ijk} B_j \bar{\partial}_{k_i} \]

(16)

with \( X \bar{\partial} Y := (\partial_X Y) - X (\partial_Y) \). Gradient expanding the left hand side of (13) to first order and integrating over the frequency yields the left-hand side of (16). The right hand side, the collision part, is usually taken to zeroth order in gradient expansion. Inserting (16) into (13) and using that combinations such as \( \int d\omega G^R \ldots G^R \) vanish, one arrives at the collision integral (with \( W_{kk'} := 2\pi n_{\text{imp}} |U(|k - k'|)|^2 \))
\[ J = -\int_{k'} W_{kk'} \frac{1}{2\pi} \int \frac{d\omega}{2\pi} (G_k^R \Delta f G_k'^A + G_k^R \Delta f G_k'^A) = \]
\[ = -\int_{k'} W_{kk'} \frac{1}{2\pi} \int \frac{d\omega}{2\pi} (G_k^R \Delta f G_k'^A + G_k'^R \Delta f G_k'^A + \ldots) \]

where in the last row only terms of second order in the interaction strength were kept. The shorthand notations \( \Delta f = f(k, x, t) - f(k', x, t) \) and \( \int \frac{d^3k'}{(2\pi)^3} = \int_{k'} \) were introduced.

In the expression \( (17) \) we also need the retarded and advanced components. For this one should take the \textit{sum} of the two Dyson equations \( (11) \), which for \( G^R(\Sigma = 0) \) after Wigner transformation leads to

\[ 2 = (\omega^+ - H^0)e^{\pm i\pi / 4} G^{\text{OR}} + G^{\text{OR}} e^{\pm i\pi / 4} (\omega^+ - H^0), \]

with \( \omega^+ := \omega + i\eta \) (to take care of the boundary conditions provided by the imaginary part of \( \Sigma^R \) when \( \Sigma \neq 0 \)) and with \( H^0 := H - \phi \). To zeroth order in gradient expansion it is solved by

\[ G^{\text{OR}} = \sum_{s=\pm} \frac{S_{bs}}{\omega^+ - \epsilon^s} \]

\[ \text{S}_{bs} := \frac{1}{2} (1 + \sigma \cdot sb) \]

where \( S \) is the spin projection operator. With this zeroth order \( G^{\text{OR}} \), the last line in \( (17) \) can be reformulated to be identical to the result derived in ref. \([21]\) and essentially also to the one derived in ref. \([19]\).

To the knowledge of the author, one finds in the literature always the zeroth order solution for \( G^{\text{OR}} \), maybe because in the common cases like spinless electrons or Zeeman-coupled electrons (with a constant magnetic field) the first order contribution to \( (18) \) (and thus to \( G^{\text{OR}} \)) vanishes. However, for a spin-orbit coupled system it does not. We find the first order contribution

\[ \delta G^{\text{OR}} = \sigma_z N b \frac{E_\theta b - B_z (\omega - a) \partial_k b}{k (\omega^+ - \epsilon^s)^2 (\omega^+ - \epsilon^-)^2} = [B_z = 0] \]

\[ = \sigma_z N \frac{E_\theta}{4k} \sum_s (-sb^{-1} - \partial_s) \frac{1}{\omega^+ - \epsilon^s}, \]

with \( E_\theta := E \cdot \hat{\theta} \) in the polar decomposition \( E = E_k \hat{k} + E_\theta \hat{\theta} \). In section \( [X] \) we show how the contribution \( (20) \) modifies the collision integral. We will also investigate, whether the corresponding correction could be an alternative source to the SHE not relying on the precession term. \([41]\)

V. COLLISION INTEGRAL TO LINEAR ORDER IN SPIN-ORBIT COUPLING

In this section the Boltzmann equation is expanded to first order in the spin-orbit coupling, as done in refs. \([19]\) and \([21]\), hence assuming \( b(k_F) \ll \epsilon_F \). The subscript \( F \) indicates the value of the corresponding quantity at the Fermi surface determined by \( a = \epsilon_F \), where \( \epsilon_F = \mu \) at low temperatures \( k_B T \ll \epsilon_F \).

The collision integral is taken to the habitual zeroth order in gradient expansion, meaning \( (17) \) with \( (19) \). To slim down the often lengthy expression for collision integrals, some more shorthand notation is introduced. \( x' \) means that the quantity \( x \) depends on primed variables such as \( k', s' \) etc, whereas \( x \) correspondingly depends on \( k, s \). For example \( S' = \frac{1}{2}(1 + \sigma \cdot s') \hat{k}' \). Also, \( \Delta x := x - x' \), for example \( \Delta \epsilon = \epsilon_k' - \epsilon_k \), or \( \Delta(sb) = sb - s'b' \).

Inserting \( (19) \) into \( (17) \) gives

\[ J_0 = -\int_{k'} W_{kk'} \frac{1}{2\pi} \sum_{ss'} \delta(\Delta \epsilon) \left[ \frac{1 + ss' \hat{b} \cdot \hat{b}'}{2} \Delta f_0 + \frac{s \hat{b} + s' \hat{b}'}{2} \cdot \Delta f \right] + X_0 \]

\[ J = -\int_{k'} W_{kk'} \frac{1}{2\pi} \sum_{ss'} \delta(\Delta \epsilon) \left[ \frac{1 + ss' B_{kk'}'}{2} \Delta f + \frac{s \hat{b} + s' \hat{b}'}{2} \cdot \Delta f_0 \right] + X. \]

with the matrix \( B_{kk'} := \hat{b}(\hat{b}')^T + \hat{b}'(\hat{b})^T - \hat{b} \cdot \hat{b}' \)[42]. Not written out in equation \( (21) \) are the principal part terms

\[ X = \int_{k'} W_{kk'} \frac{1}{2\pi} \sum_{ss'} \mathcal{D} \left( \frac{1}{\Delta \epsilon} \right) \left[ \frac{ss' \hat{b} \times \hat{b}'}{2} \cdot (\Delta f - \sigma \Delta f_0) - \sigma \cdot \frac{\Delta (sb)}{2} \times \Delta f \right] \]

\[ (22) \]
which are not considered to be a part of the elastic collision integral but are regarded as renormalization corrections. In the literature such terms are usually left out (however, see ref. [37]) and it is beyond the scope of the present paper to discuss them.

The delta functions $\delta(\epsilon^+_k - \epsilon^+_l)$ connecting Fermi surfaces at different $|k|$ make it difficult to find a analytical solution. However, in the considered limit $b(k_F) \ll \epsilon_F$ one can use the expansion

$$\delta(\Delta \epsilon) = \delta(\Delta a) + \Delta(\pi b) \delta'(\Delta a) + O(\lambda^2)$$

(23)

after which one is left with the spin-independent delta function $\delta(a_k - a_{k'})$ implying $|k'| = |k|$. With this expansion the collision integral reads

$$J = - \int_{k'} W_{kk'} \left[ \delta(\Delta a) \Delta f_0 + \delta'(\Delta a) \Delta b \cdot \Delta f \right]$$

(24)

The terms with $\delta'(\Delta a) = -\partial_a \delta(\Delta a)$ are made sense of by integration by parts.

If $f = O(\lambda)$ (i.e. if the polarization vanishes as $\lambda \to 0$), the term indicated as of order $O(\lambda^2)$ can be neglected to linear order in $\lambda$. This resulting collision integral is essentially the one found in ref. [21] and is similar to the one in ref. [19].

In section VI we discuss corrections to the collision integral when one goes beyond zeroth order in gradient expansion.

VI. SOLVING THE BOLTZMANN EQUATION

We now set out to solve the uniform, steady state Boltzmann equation

$$2\sigma \cdot f + E \cdot \partial_a f = - \int_{k'} W_{kk'} \left[ \delta(\Delta a) \Delta f_0 + \delta'(\Delta a) \Delta b \cdot \sigma \Delta f_0 \right]$$

(25)

without implementing the assumption of perturbativeness in $\lambda$, to be discussed in sec VIII. The distribution function $f = f^{\text{eq}} + f^{(E)}$ is linearized only in the electric field and not in the spin-orbit coupling.

The distribution $n^\pm = f_0^\pm f_\pm$ of respective spin band is in equilibrium given by the Fermi-Dirac (FD) distribution. The equilibrium distribution is therefore given by

$$f_0^\pm \equiv f_{FD}^\pm = f_{FD}^\pm (\epsilon^\pm - \mu) \quad \text{i.e.} \quad f^{\text{eq}} = \sum_{\pm} S_{b}\pm f_{FD}^\pm (\epsilon^\pm - \mu),$$

(26)

with vanishing inter-band elements $f_b^\sigma = f_b^\bar{\sigma} = 0$. Time reversal symmetry requires the real space equilibrium polarization $f^{\text{eq}} = f_k^\pm f^{\text{eq}}(k)$ to be zero, which also follows trivially from the vanishing angular part of the integral. The real space spin current, on the other hand, need not vanish since it is even under time reversal symmetry. For $|N| \neq 1$ the real space spin current is trivially zero, but for $N = \pm 1$ we find $j_y = \mp j_x^\pm = -m^2 \lambda^3 / 2\pi + O(\lambda^5)$ for a quadratic dispersion $a = k^2 / 2m$.

The equilibrium distribution is from now on taken to linear order in $\lambda$, i.e.

$$f_0^\pm = \sum_{\pm} f_{FD}^\pm (\epsilon^\pm - \mu) = f_{FD}^\pm (a - \mu) + O(\lambda^2) \Rightarrow f_b^{\text{eq}} = \frac{b \partial_a f_{FD}^\pm (a - \mu) + O(\lambda^2)}{2}$$

(27)

where $f_{FD} \equiv f_{FD}^\pm (a - \mu)$ from now on. From (27) one sees that a small spin-orbit coupling does not change the charge density but induces a small polarization at the Fermi surface. The distribution $f^{\text{eq}} = f_{FD} + \sigma \cdot b \partial_a f_{FD}$ satisfies (25) for $E = 0$.

The charge part of (25) does not depend on the polarization. When a uniform, static electric field is applied, one finds the usual solution $f_0^{(E)} = -\tau_a E \epsilon \partial_k f_{FD}$ where $\tau_a$ is the transport relaxation time. Gathering the known terms on the left-hand side one can write the polarization part of the equation as

$$E \cdot \partial_k f^{\text{eq}} + \int_{k'} W_{kk'} \delta'(\Delta a) \sigma \cdot \Delta b \Delta f_0^{(E)} = 2b \times f^{(E)} - \int_{k'} W_{kk'} \delta(\Delta a) \Delta f^{(E)}.$$  

(28)
It turns out (see the appendix) that the equation can be written in the form

$$F(E_k \hat{b} - E_\theta \hat{c}) + G(E_k \hat{b} + E_\theta \hat{c}) = 2b \times f^{(E)} - \int_{q'} K \Delta f^{(E)}|_{k' = k},$$

(29)

with the shorthand \(\int_{q'} := \int \frac{d^2 q'}{2\pi}\). The functions \(F\) and \(G\) depend on \(k\) and are proportional to \(\lambda\). They do not depend on \(\theta\), on \(E\), on the impurity concentration \(n_{\text{imp}}\) or on the overall strength of the impurity potential \(U\). However, they depend on the range of the potential through dimensionless fractions of the Fourier components of the functions

$$K(k, \Delta \theta) := D(a)W_{kk} |_{k' = k} =: \sum_m e^{im\Delta \theta} K_m$$

$$\tilde{K}(k, \Delta \theta) := D(a)knu[\partial_\theta W_{kk'}] |_{k' = k} =: \sum_m e^{im\Delta \theta} \tilde{K}_m.$$  

(30)

\[\text{Eqn:}\]

\[\text{FandG}\]

\[\text{angin-dep}\]

\[\text{dep}\]

\[\text{comp}\]

\[\text{n1}\]

\[\text{inc2}\]

\[\text{matrixb}\]

\[\text{inc}\]

Particularly, for \(N = 1\) we find for a general dispersion \(a \propto k\hat{c}\) that

$$F = \lambda \left[ \frac{\partial_a f_{FD}}{2} \left( (\zeta - 2) \tau_{1\tau}^{-1} + \zeta \tau_{1\tau}^{-1} - 2 \tau_{1\tau} \tau_{1\tau}^{-1} \tau_{01}^{-1} - \tilde{z}_{01}^{-1} + \tilde{z}_{12}^{-1} \right) \tau_{1\tau} + \frac{k \partial_\delta \partial_{\theta} f_{FD}}{2} (1 + \tau_{1\tau} \tau_{1\tau}^{-1}) \right]$$

$$G = 0$$

(31)

with \(\tau_{1\tau} = K_0 - K_1\) and introducing shorthands \(\tau_{12}^{-1} := K_1 - K_2, \tau_{01}^{-1} := \tilde{K}_0 - \tilde{K}_1, \text{ and } \tau_{12}^{-1} := \tilde{K}_1 - \tilde{K}_2\). We find that \(G = 0\) also when \(b\) is not proportional to \(k\). The vanishing of \(G\) is going to imply the vanishing of the spin Hall effect for the Rashba coupling.

The combination \(E_k \hat{b} + E_\theta \hat{c}\) has a winding \(N \pm 1\). Particularly, for the Rashba case \(\hat{b} = \hat{\theta}\) (i.e. \(N = 1\)) one has

$$E_k \hat{b} - E_\theta \hat{c} = \left( \hat{b} (k)^T - \hat{c} (\hat{\theta})^T \right) E = \left( \begin{array}{cc} -\sin 2\Delta \theta & \cos 2\Delta \theta \\ \cos 2\Delta \theta & \sin 2\Delta \theta \end{array} \right) E$$

$$E_k \hat{b} + E_\theta \hat{c} = \left( \begin{array}{cc} 0 & -1 \\ 1 & 0 \end{array} \right) E,$$

(32)

\[\text{i.e. the left-hand side of (30)}\]

has an angularly independent term.

The solution can be found by Fourier decomposition in the basis \(\{ \hat{b}, \hat{c}, \hat{z} \}\)

$$f^{(E)} = \sum_n e^{i\theta} (\hat{b} f_{bn} + \hat{c} f_{cn} + \hat{z} f_{zn}) = \sum_n e^{i\theta} \left( \begin{array}{c} \hat{b} \\ \hat{c} \\ \hat{z} \end{array} \right) \left( \begin{array}{c} f_{bn} \\ f_{cn} \\ f_{zn} \end{array} \right),$$

(33)

where the Fourier coefficients \(\{ f_{bn}, f_{cn}, f_{zn} \}\) of course only depend on \(k\) and not on \(\theta\). With \(E := E_x + iE_y\) one has

$$2(E_k \hat{b} \pm E_\theta \hat{c}) = \epsilon^{i\theta} \epsilon^* (\hat{b} \pm i\hat{c}) + \epsilon^{-i\theta} \epsilon^* (\hat{b} \mp i\hat{c})$$

and therefore the left-hand side of (29) can be written as

$$\frac{1}{2} \epsilon^{i\theta} \epsilon^* \left( \hat{b} \hat{c} \hat{z} \right) \left( \begin{array}{c} F + G \\ iG - iF \end{array} \right) + \text{c.c.,} \quad \left(34\right)$$

which contains only the \(n = 1\) Fourier component and the complex conjugate \(n = -1\) component. This is going to imply that \(f_{bn}, f_{cn}, f_{zn} = 0\) for \(|n| \neq 1\). (Choosing a cartesian basis in (29), in contrast, couples the equation for component \(n\) with the components \(n \pm N\).) This fact has some direct implications for the electric field induced contributions to the real space densities. For example, the real space density of z-spins \(f_z^{(E)}\) is trivially zero. For \(|N| \neq 1\) the in-plane components \(f_x^{(E)}\) and \(f_y^{(E)}\) also vanish trivially in real space, whereas for \(|N| = 1\) they can be nonzero. The real space spin Hall current \(j^z\) can be nonzero for all \(N\), whereas the contribution to \(j^x\) and \(j^y\) vanishes trivially for all \(N\).

On the right-hand side of (28) we find

$$- \int_{q'} K \Delta f^{(E)}|_{k' = k} = - \sum_n e^{i\theta} \left( \hat{b} \left( f_{bn} - i f_{cn} \right) K \left( 1 - \cos N \Delta \theta \cos n \Delta \theta \right) + i f_{zn} f_{zn} K \sin N \Delta \theta \sin n \Delta \theta \right) + \hat{c} \left( f_{bn} - i f_{cn} \right) K \left( 1 - \cos N \Delta \theta \cos n \Delta \theta \right) + \hat{z} f_{zn} f_{zn} K \left( 1 - \cos n \Delta \theta \right).$$

Here, \(\hat{b}' = \hat{b} \cos N \Delta \theta - \hat{c} \sin N \Delta \theta\) was used and terms odd in \(\Delta \theta\) were left out, using that \(K\) is even in \(\Delta \theta\). Including the precession term \(2b(\hat{z} f_{\hat{c}} - \hat{c} f_{\hat{z}})\) the equation for the \(n = 1\) Fourier components of \(f^{(E)}\) becomes
To the knowledge of the author it has not been related to the finiteness of the in-plane polarization like done in the vanishing of the SHE for the Rashba case has been found by numerous previous studies (see the introduction). The real space spin density \( \sigma \) for the real space spin current. As in ref. 19 one recovers in the clean limit \( \tau_{\cos}^{-1} = K_0 \ll k_F \lambda \) a universal spin Hall conductivity \( \sigma_{\text{SH}} = \frac{K_0}{2} \), whereas \( \sigma_{\text{SH}} \) decreases to zero in the opposite (dirty) limit.

For the case \( N = \pm 1 \) one has for arbitrary impurity range that \( \tau_{\cos} = \pm \tau_{\sin} =: 2 \tau_{02} \). The determinant \( 4 b^2 \tau_{\cos}^{-1} + \tau_{tr}^{-1} (\tau_{\cos}^{-2} - \tau_{\sin}^{-2}) \) of the matrix in (35) becomes singular at \( b = 0 \). For \( N = 1 \) we find the solution

\[
\begin{align*}
\hat{f}_{b1} &= -E^* \left( \tau_{02} (F + G) + \frac{G}{4 \tau_{tr} b^2} \right) \\
\hat{f}_{\bar{a}1} &= -i E^* \frac{G}{4 \tau_{tr} b^2} \\
\hat{f}_{\bar{z}1} &= -i E^* \frac{G}{2 b}.
\end{align*}
\]

The real space density \( \int_k \hat{f}_z \) must vanish trivially as noted after equation (34). The real space density of the in-plane spin components is nonzero

\[
\int_k (\hat{b} \hat{f}_b + \hat{c} \hat{f}_c) = -E \times E \int da \int \frac{G}{2 \tau_{tr} b^2}.
\]

According to (31), \( G = 0 \) for \( N = 1 \) for arbitrary dispersion and arbitrary range of impurities according. Thus, \( \hat{f}_z = 0 \) for a Rashba coupling, implying a zero spin Hall current. A similar analysis applies to \( N = -1 \), e.g. for the linear Dresselhaus coupling, since a model of winding \(-N\) is related to one of winding \(N \) through reflection (say along the \( x \)-axis).

If for the Rashba coupling there was a nonzero spin Hall effect, i.e. \( G \neq 0 \), then \( \hat{f}_z \) and consequently the spin Hall current would be independent of \( \lambda \) (since in general, \( G \propto \lambda \)). Furthermore, the in-plane components \( \hat{f}_x \) and \( \hat{f}_y \) of the polarization would diverge as \( \lambda^{-1} \) as \( \lambda \to 0 \), i.e. one would not recover an unpolarized distribution when sending the spin-orbit coupling to zero. However, in the derivation of the Boltzmann equation there were only assumptions of \( \lambda \) and \( f \) being small enough, no assumptions of them not being too small. Therefore, to the extent that a diverging polarization in such a case is an unthinkable result, the vanishing of the SHE for the Rashba case is a natural implication.

VII. GENERAL ARGUMENTS FOR A VANISHING SHE

The vanishing of the SHE for the Rashba case has been found by numerous previous studies (see the introduction). To the knowledge of the author it has not been related to the finiteness of the in-plane polarization like done in the argument above. In linear response studies general arguments have been given [24, 28], where from \( [\sigma_y, \lambda (p \times \sigma)_z] = 2i \lambda p_y \sigma_z \) it is noted that for Heisenberg operators

\[
\frac{d}{dt} \hat{\sigma}_y = -i [\hat{\sigma}_y, \hat{H} + \hat{V}_{\text{imp}}] = 2 \lambda \hat{p}_y \hat{\sigma}_z = 2 \lambda m_{\text{imp}} \hat{j}_y
\]
for non-magnetic impurities. The steady state condition $\frac{\partial}{\partial t} \hat{\sigma}_y = 0$ forces the spin Hall current $\hat{j}_y$ to be zero. A similar argument applies to $\hat{j}_x$.

The analog to this argument in the Boltzmann approach can be established for the real space densities. In phase space, $(s \times b)^y = b_x s^z = j^z y b_x / v_{0y}$. Only for $N = \pm 1$ does one have a constant fraction $b_x / v_{0y} = \mp \lambda m$. According to (40) one has $\partial_t s^y = -2(s \times b)^y - E \cdot \partial_y s^y + \mathcal{J}$ in the uniform case. In the integration over momentum the last two terms vanish, resulting in $\partial_t s^y = \pm 2\lambda m j^z_y$ in real space for $N = \pm 1$. Likewise, $\partial_t s^x = -2\lambda m j^z_x$. In a steady state, $\partial_t s = 0$ implies $\hat{j}^y = 0$.

In phase space, on the other hand, the steady state condition $0 = \partial_t s^y = -2(s \times b)^y - E \cdot \partial_y s^y \ldots$ does not imply a vanishing $j^y_x$. We could have had $G \neq 0$ as long as $\int da \, Dv_G G/b = 0$ guaranteed the vanishing in real space. However, in the previous section we found that $\hat{j}^y = 0$ also in phase space.

VIII. ASSUMPTION OF LINEAR RESPONSE IN THE SPIN-ORBIT COUPLING

We are now going to study the implications of a basic assumption, namely that the steady-state response of a spin-orbit coupled system in an electric field is perturbative in the small parameter $\lambda$ ($v_F$ is kept constant), analogously to the usual assumption of linear response in the electric field strength $E$. For the latter assumption it means that one can expand the solution $f^{eq} + f^{(E)} + f^{(E^2)} + \ldots$ in nonnegative powers in the electric field and solve the equation iteratively by solving equations that are homogenous in orders of $E$, see e.g. equation (28). With the assumption now to be studied, the same is expected to apply also for the spin-orbit coupling parameter $\lambda$ ($v_F$ is kept constant), wherefore the solution can be expanded in powers of $E$ and $\lambda$

$$f = \sum_{m,n \geq 0} f^{(\lambda^m E^n)}$$

(41)

assuming that the solution is analytic both in $\lambda$ and $E$.

The equations are going to be solved order by order in both parameters as illustrated in (45). In the expansion of the Boltzmann equation in a small spin-orbit coupling, there is in this case no ambiguity about which terms to include in a given equation. This should be contrasted with the previous section, where we chose to include the precession term $2b \times f$—a term of order $O(\lambda^2)$—though we discarded other terms of the same order, for example in (23). The reproduced results seem to be based on hand-picking terms with physical insight.

IX. BOLTZMANN EQUATION WITHOUT THE PRECESSION TERM

Due to the assumption in sec. VIII not only the equation but also the solution is linearized in the spin-orbit coupling. Together with the habitual linearization in the electric field this means that we consider

$$f = f^{(0)} + f^{(\lambda)} + f^{(E)} + f^{(\lambda, E)}$$

(42)

where the superscripts denote the order in $\lambda$ and $E$, respectively (e.g. $f^{(E)} \propto \lambda^0 E^1$). The equilibrium distribution is $f^{eq} = f^{(0)} + f^{(\lambda)}$, where $f^{(0)} = 1 f_{FD}$.

The left-hand side of the Boltzmann equation (8) is in the static, uniform case

$$\frac{df}{dt} = E \cdot \partial_k f + 2\sigma \cdot \hat{f} \times b^{\mathcal{O}(\lambda^2)}$$

(43)

where the precession term must be neglected to order $\lambda$. However, leaving out the precession term leads to some formal trouble in the case $N = ±1$. The derivative $E \cdot \partial_k f = e^{i\theta} (E_x - i E_y) (\partial_k + ik^{-1} \partial_\theta) + c.c.$ comes with a winding number $±1$. For a spin-orbit coupled system the equilibrium polarization $f^{eq} = f(E = 0)$ has a also winding number, here $N$. Thus, the combination $E \cdot \partial_k f$ comes with terms of winding $N \pm 1$. For $N = 1$ (e.g. Rashba) or $N = -1$ (e.g. linear Dreselhaus) the left hand side therefore contains terms without angular dependence, as seen in (28). Such terms cannot be matched by the collision integral, essentially because an equation like $1 = \int d\theta \, (f(\theta) - f(\theta'))$ has no solution. (A collision integral cannot be a source/drain.)

This lack of solution might be related to the discarding of the principal part terms $X$ in (21), but we have not been able to investigate this. As a simple remedy, we introduce instead a small spin relaxation term, which could come from spin relaxation processes not related to the spin-orbit coupling. The Boltzmann equation then reads...
\[ \sigma \cdot \tau_{S}^{-1} f + E \cdot \partial_{k} f = - \int_{k'} W_{kk'} \left[ \delta(\Delta a) \Delta f + \delta'(\Delta a) \sigma \cdot \Delta \Delta f_{0} \right] \]  \tag{44}

where it is assumed that \( \tau_{S}^{-1} \) is much smaller than \( \tau_{tr}^{-1} \), is independent of \( \lambda \) and is a number though in general it could be a matrix.

We now solve the Boltzmann equation \( \tag{41} \) order by order in \( \lambda \) and \( E \) as shown in equation \( \tag{43} \) LE

\[
\begin{align*}
\lambda^{0} E^{0} : & \quad 0 = - \int_{k'} W_{kk'} \delta(\Delta a) \Delta f^{(0)} \\
\lambda^{1} E^{0} : & \quad \sigma \cdot \tau_{S}^{-1} f^{(\lambda)} = - \int_{k'} W_{kk'} \left[ \delta(\Delta a) \Delta f^{(\lambda)} + \delta'(\Delta a) \sigma \cdot \Delta \Delta f_{0}^{(\lambda)} \right] \\
\lambda^{0} E^{1} : & \quad E \cdot \partial_{k} f^{(0)} = - \int_{k'} W_{kk'} \delta(\Delta a) \Delta f^{(E)} \\
\lambda^{1} E^{1} : & \quad \sigma \cdot \tau_{S}^{-1} f^{(\lambda,E)} = - \int_{k'} W_{kk'} \left[ \delta(\Delta a) \Delta f^{(\lambda,E)} + \delta'(\Delta a) \sigma \cdot \Delta \Delta f_{0}^{(\lambda,E)} \right]. \tag{45}
\end{align*}
\]

Note that terms known to be zero were left out \( \tag{45} \). We are out to find \( f^{(\lambda,E)} \), which is of order \( \lambda^{1} E^{1} \) and therefore the first contribution that incorporates the combined effects of an electric field and spin-orbit coupling \( \tag{46} \). However, to solve the \( \lambda^{1} E^{1} \) equation one needs to solve the previous equations to find out \( f^{(\lambda)} \) and \( f^{(E)} \).

The \( \lambda^{0} E^{0} \) equation is consistent with \( f^{(0)} = 1 f_{FD} \) from \( \tag{24} \). The spin-relaxation term in the \( \lambda^{1} E^{0} \) equation decreases the equilibrium polarization in \( \tag{27} \) into \( f^{(\lambda)} = \gamma \sigma \cdot \hat{b}_{\lambda} f_{FD} \) with \( \gamma := (1 + \tau_{S}^{-1} \tau_{tr})^{-1} \approx 1 \). The \( \lambda^{0} E^{1} \) equation is solved by \( f^{(E)} = -1 \tau_{tr} E \cdot \partial_{k} f_{FD} \). So finally at the \( \lambda^{1} E^{1} \) equation one knows already the terms \( E \cdot \partial_{k} f^{(\lambda)} \) and \( \int_{k'} W_{kk'} \delta'(\Delta a) \Delta \sigma \cdot f^{(E)} \). Collecting these contributions on the left-hand side we get an equation of the same form as \( \tag{29} \), but with the spin precession term replaced by the spin relaxation term, and with \( F \) and \( G \) modified due to the factor \( \gamma \) in \( E \cdot \partial_{k} f^{(\lambda)} \). The equation for the \( n = 1 \) Fourier coefficients turns into

\[
f^{eq}_{1 - \pi \over 2} = \left( \begin{array}{ccc}
F + G & iG - iF \\
0 & 0
\end{array} \right) = - \left( \begin{array}{ccc}
\tau_{S}^{-1} + \tau_{\cos}^{-1} & i\tau_{\sin}^{-1} & 0 \\
-i\tau_{\sin}^{-1} & \tau_{S}^{-1} + \tau_{\cos}^{-1} & 0 \\
0 & 0 & \tau_{S}^{-1} + \tau_{tr}^{-1}
\end{array} \right) \left( \begin{array}{c}
f_{k1} \\
\delta_{1} \\
f_{x1}
\end{array} \right) \tag{46}
\]

For \( N = \pm 1 \) one has \( \tau_{\cos} = \pm \tau_{\sin} \) for a general impurity potential, leading the determinant of the matrix to be zero unless \( \tau_{S}^{-1} = 0 \). (With \( \tau_{S}^{-1} = 0 \) there is either no solution when \( G \neq 0 \) or multiple solutions when \( G = 0 \).) For \( |N| \neq 1 \) one has \( \tau_{\cos} \neq \tau_{\sin} \) for realistic impurity potentials, wherefore \( \tau_{S}^{-1} = 0 \) is not needed.

Important to retain is that the matrix does not depend on \( \lambda \). The polarization \( f^{(\lambda,E)} \) is therefore proportional to \( \lambda \). Clear is also that \( f_{z} = 0 \) and the spin Hall current \( j^{z} \) are zero—for an arbitrary spin-orbit coupling.

For \( N = \pm 1 \) we can adopt the derivation in sec. \( \tag{11} \) to show that \( \partial_{s} s_{y} = \pm m \lambda j_{y}^{a} - \tau_{S}^{-1} s_{y} \) in real space. For our steady state case we therefore find \( s^{y} \propto j_{y}^{a} = 0 \) in real space for \( N = \pm 1 \). Likewise, \( s_{x} = 0 \). For \( |N| \neq 1 \) the real space polarization is trivially zero (see under equation \( \tag{34} \)). Summarizing we have that for no \( N \) in the perturbative case does the electric field alter any real space densities to lowest order in \( \lambda \). The only nonzero real space densities are the equilibrium spin currents \( j^{x} \) and \( j^{y} \) for \( |N| = 1 \). From \( f^{eq} = f_{FD} + \gamma \sigma \cdot \hat{b}_{\lambda} f_{FD} \) for \( N = \pm 1 \) we find \( j_{x}^{y} = \mp j_{y}^{y} = 1 \pi (\gamma - 1) b_{y} k_{F} \).

\[
X. \quad \text{ELECTRIC FIELD INDUCED CORRECTIONS TO THE COLLISION INTEGRAL}
\]

The precession term seemed so far like the only term that could involve the \( f_{z} \) component and lead to nonzero spin current \( j^{z} \). In this section we are going to see that the electric field \( E \) modifies the collision integral in a way that involves the \( f_{z} \) component. However, the corrections turns out to be of order \( \lambda^{3} \).

In trying to incorporate in our Boltzmann equation all terms present to first order in our parameters we so far left out terms by gradient expanding the right-hand side of the Dyson equation \( \tag{13} \) for \( G^{R} \) only to zeroth order and not to first order in the electric field. First order corrections have been accounted for example in the case of electron-phonon renormalization of the ac conductivity \( \tag{38} \) (see also \( \tag{33} \)) and have also been discussed in the SHE and AHE literature (see e.g. refs. \( \tag{18} \) or \( \tag{20} \)). However, a derivative such as \( 2E \cdot \partial_{b} S_{zb} = sk^{-1} E_{q} \partial_{b} \hat{b} \cdot \sigma \), which occurs in the derivation of these corrections, gives a vector that remains in the plane. The collision integral becomes more complicated but does not involve the \( f_{z} \) component.

The contribution discussed in this paper comes about in a slightly subtler way, and has to the knowledge of the author not been discussed previously. It comes from gradient expanding the equation of motion also for the retarded Green’s function \( G^{0R} \), which results in the correction \( \delta G^{0R} \) given by \( \tag{20} \). With \( B_{z} = 0 \) one obtains...
\[
\delta J = - \int_{k'} \frac{W_{kk'}}{2\pi} \int \frac{d\omega}{2\pi} (\delta G^0_{k\omega} \Delta f G^0_{k'\omega} + G^0_{k\omega} \Delta f \delta G^0_{k'\omega} + G^0_{k'\omega} \Delta f \delta G^0_{k\omega} + \delta G^0_{k'\omega} \Delta f G^0_{k\omega}) = \\
= - \frac{1}{8} \sum_{ss'} \int \frac{W_{kk'}}{k'} \left[ (\sigma_z \Delta S^s + S' \Delta f \sigma_z)E_\theta (\partial_{\sigma} - sb^{-1}) \delta(\Delta \epsilon) + (\sigma_z \Delta S + S \Delta f \sigma_z)E_{\theta'} (\partial_{\sigma'} - s' b'^{-1}) \delta(\Delta \epsilon) \right] = \\
= \sigma \frac{1}{2} \int k' \delta''(\Delta \epsilon) (W_{kk'} [\hat{z} M \cdot \Delta f + M \Delta f_z])
\]

where for the last line the expansion (23) was used and where

\[
M(k, k') := k^{-1} E_\theta b' + k'^{-1} E_{\theta'} b.
\]
The term $\int_{k'} W_{kk'} \delta'(\Delta \alpha) \Delta \mathbf{b} \cdot \sigma \Delta f_{0}^{(E)}$ is here for brevity only evaluated for a point-like impurity potential, i.e. $W_{kk'} = W$ constant, and constant density of states $D(\omega) = m/2\pi$. Hence

$$\tau_{tr}^{-1} = \int_{k'} \delta'(\Delta \alpha) W_{kk'}(1 - \cos(\Delta \theta)) = DW \tag{A2}$$

With $\delta'(\Delta \alpha) = \partial_{\alpha} \delta(\Delta \alpha) = -\partial_{\alpha} \delta(\Delta \alpha)$ a partial integration gives

$$\int_{k'}^{} W \delta'(\Delta \alpha) \Delta \mathbf{b} \Delta f_{0}^{(E)} = \int \frac{d\theta'_{\Gamma}}{2\pi} \delta(\Delta \alpha) \partial_{\Gamma} (DW \Delta \mathbf{b} \Delta f_{0}^{(E)}) =$$

$$= \lambda \frac{\lambda}{2} \int \frac{d\theta'_{\Gamma}}{2\pi} \delta(\Delta \alpha) \left[ k_{\alpha} \partial_{\Gamma} f_{\Gamma}^{b} + \partial_{\alpha}(k') \partial_{\Gamma} f_{\Gamma}^{d} \right]$$

$$= -\delta_{N,1} \frac{\lambda}{2} (E_{b} + N E_{b}^{c})(k_{\alpha} \partial_{\Gamma} f_{\Gamma}^{b} + \partial_{\alpha} f_{\Gamma}^{d}) =$$

$$= -\delta_{N,1} \frac{\lambda}{2} (E_{b} + N E_{b}^{c})(k_{\alpha} \partial_{\Gamma} f_{\Gamma}^{b} + \partial_{\alpha} f_{\Gamma}^{d}) \tag{A3}$$

where it was used that $\delta'_{\Gamma} = \cos N \Delta \theta - \sin N \Delta \theta$ and $k' = \cos \Delta \theta - \sin \Delta \theta$. In the last line it was used that $\partial_{\alpha} \partial_{\Gamma} = \partial_{\alpha} \left( \frac{\partial_{\Gamma}}{k_{\alpha}} \right) = (\partial_{\alpha} v_{0}) \partial_{\alpha} + v_{0} \partial_{\alpha} = \frac{\partial_{\alpha}}{k_{\alpha}} \partial_{\alpha} + \partial_{\alpha} \partial_{\alpha}$ for $v_{0} \propto k_{\alpha}^{-1}$. For a non-constant $D$ (i.e. for $\xi \neq 2$) the result in [A3] is modified. Note also that it is only for point-like impurities that the contribution [A3] vanishes for $|N| \neq 1$.

Adding up [A1] and [A3] one obtains for $N = 1$ that $F = \frac{1}{2} \lambda (\xi - 2) \partial_{\Gamma} f_{\Gamma} + \frac{1}{2} \lambda \gamma k_{\alpha} \partial_{\Gamma} f_{\Gamma}^{d}$ and $G = \lambda (\gamma - 1)(\partial_{\alpha} f_{\Gamma}^{d} + \frac{1}{k_{\alpha}} k_{\alpha} \partial_{\Gamma} f_{\Gamma}^{d})$. For $|N| \neq 1$ the contribution [A3] vanishes and one gets for example $G = F = \lambda (\gamma - 1) \partial_{\Gamma} f_{\Gamma}$, needed for the result [37].
Note also that this term is equally shared between the two bands; \( \langle \hat{b}_s| \{v, f\} | \hat{b}_s \rangle = n^s v^s + k^{-1} b f_\theta \).

Note that if one in contrast to equation (18) takes the difference of the equations (11), the equation for \( G^0_R \) is identical to (13) with \( \Sigma = 0 \). This equation does not determine \( G^0_R \), but given (18), the precession term (in the equation for \( G^0_R \)) implies the presence of (20) to first order in electromagnetic fields.

The structure of B is relevant for graphene (one Dirac cone). Not surprisingly, an equivalent structure is found in ref. [36]. We note that one gets a different matrix B if one instead uses the nonequilibrium statistical operator method, used for example in ref. [37]. This difference, to be discussed elsewhere (J. Kailasvuori and M. Lüffe, in preparation), has no influence on the present paper since the term involving B does not contribute to first order in spin-orbit coupling.

The quasiclassical approach of ref. [19] makes a straightforward comparison not obvious, but it seems like there is no analogue of the term containing \( \partial \Delta \tilde{f}_0 \) that we obtain after integration by parts.

To compare with ref. [19], note that \( \partial_{\nu'} W_{kk'}|_{k' = k} = (v_0 k)^{-1} \tan^2(\Delta \theta/2) \partial_{\nu'} W_{kk'}|_{k' = k} \). For example \( f^{(E)} = 0 \) since the electric field alone leads to no polarization, therefore \( \tau_0^{-1} f \) could be left out in the equations of order \( \lambda^0 E^z \).

Note that \( f^{(\lambda^2)} \) or \( f^{(E^2)} \) cannot contribute to the spin Hall effect. Therefore we do not need consider them, though one of them need not be subleading to \( f^{(\lambda, E)} \).
